# How to find eigenValues ?

Our next objective is to obtain a general procedure for finding eigenvalues and eigenvectors of an  $n \times n$  matrix  $A$ . We will begin with the problem of finding the eigenvalues of  $A$ . Note first that the equation  $A\mathbf{x} = \lambda\mathbf{x}$  can be rewritten as  $A\mathbf{x} = \lambda I\mathbf{x}$ , or equivalently, as

$$(\lambda I - A)\mathbf{x} = \mathbf{0}$$

For  $\lambda$  to be an eigenvalue of  $A$  this equation must have a nonzero solution for  $\mathbf{x}$ .

$$A\mathbf{x} = \lambda\mathbf{x}$$

$$A\mathbf{x} - \lambda\mathbf{x} = \mathbf{0}$$

$$(A - \lambda I)\mathbf{x} = \mathbf{0}$$

$$(\lambda I - A)\mathbf{x} = \mathbf{0}$$

For the above equation to be true, and  $\mathbf{x}$  not a zero vector (condition for eigen vector),

then  $(\lambda I - A)$  must be a singular matrix (not invertible).

See: invertible matrix theorem (corollary of (d))

# How to find eigenValues ?

## The Invertible Matrix Theorem

Let  $A$  be a square  $n \times n$  matrix. Then the following statements are equivalent. That is, for a given  $A$ , the statements are either all true or all false.

- a.  $A$  is an invertible matrix.
- b.  $A$  is row equivalent to the  $n \times n$  identity matrix.
- c.  $A$  has  $n$  pivot positions.
- d. The equation  $A\mathbf{x} = \mathbf{0}$  has only the trivial solution.
- e. The columns of  $A$  form a linearly independent set.
- f. The linear transformation  $\mathbf{x} \mapsto A\mathbf{x}$  is one-to-one.
- g. The equation  $A\mathbf{x} = \mathbf{b}$  has at least one solution for each  $\mathbf{b}$  in  $\mathbb{R}^n$ .
- h. The columns of  $A$  span  $\mathbb{R}^n$ .
- i. The linear transformation  $\mathbf{x} \mapsto A\mathbf{x}$  maps  $\mathbb{R}^n$  onto  $\mathbb{R}^n$ .
- j. There is an  $n \times n$  matrix  $C$  such that  $CA = I$ .
- k. There is an  $n \times n$  matrix  $D$  such that  $AD = I$ .
- l.  $A^T$  is an invertible matrix.

Lay, 4th, pg112 (Ch2.3)

The Invertible Matrix Theorem divides the set of all  $n \times n$  matrices into two disjoint classes: the invertible (nonsingular) matrices, and the noninvertible (singular) matrices. Each statement in the theorem describes a property of every  $n \times n$  invertible matrix. The *negation* of a statement in the theorem describes a property of every  $n \times n$  singular matrix. For instance, an  $n \times n$  singular matrix is *not* row equivalent to  $I_n$ , does *not* have  $n$  pivot positions, and has linearly *dependent* columns.

# Determinant and Invertibility

## THEOREM 4

A square matrix  $A$  is invertible if and only if  $\det A \neq 0$ .

Theorem 4 adds the statement “ $\det A \neq 0$ ” to the Invertible Matrix Theorem. A useful corollary is that  $\det A = 0$  when the columns of  $A$  are linearly dependent. Also,  $\det A = 0$  when the *rows* of  $A$  are linearly dependent. (Rows of  $A$  are columns of  $A^T$ , and linearly dependent columns of  $A^T$  make  $A^T$  singular. When  $A^T$  is singular, so is  $A$ , by the Invertible Matrix Theorem.) In practice, linear dependence is obvious when two columns or two rows are the same or a column or a row is zero.

Lay, pg171 (Ch3.2)

### Clever idea:

The determinant transforms the original problem of  $(A - \lambda I)x = 0$ , an equation with two unknowns  $\lambda, x$  into a polynomial with only 1 unknown  $\lambda$ . Allowing us to solve first for the eigen value  $\lambda$ , the roots of the polynomial. The polynomial is called the “characteristic equation” of  $A$ .

Since  $(A - \lambda I)$  is a singular matrix (NOT invertible), therefore

$$\det(A - \lambda I) = 0$$

# Characteristic Eqn and Polynomial

**EXAMPLE 1** Find the eigenvalues of  $A = \begin{bmatrix} 2 & 3 \\ 3 & -6 \end{bmatrix}$ .

**SOLUTION** We must find all scalars  $\lambda$  such that the matrix equation

$$(A - \lambda I)\mathbf{x} = \mathbf{0}$$

has a nontrivial solution. By the Invertible Matrix Theorem in Section 2.3, this problem is equivalent to finding all  $\lambda$  such that the matrix  $A - \lambda I$  is *not* invertible, where

$$A - \lambda I = \begin{bmatrix} 2 & 3 \\ 3 & -6 \end{bmatrix} - \begin{bmatrix} \lambda & 0 \\ 0 & \lambda \end{bmatrix} = \begin{bmatrix} 2 - \lambda & 3 \\ 3 & -6 - \lambda \end{bmatrix}$$

By Theorem 4 in Section 2.2, this matrix fails to be invertible precisely when its determinant is zero. So the eigenvalues of  $A$  are the solutions of the equation

$$\det(A - \lambda I) = \det \begin{bmatrix} 2 - \lambda & 3 \\ 3 & -6 - \lambda \end{bmatrix} = 0$$

## Determinant of 2x2 matrix

### THEOREM 4

Let  $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ . If  $ad - bc \neq 0$ , then  $A$  is invertible and

$$A^{-1} = \frac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$

If  $ad - bc = 0$ , then  $A$  is not invertible.

$$\det A = ad - bc$$

Theorem 4 says that a  $2 \times 2$  matrix  $A$  is invertible if and only if  $\det A \neq 0$ .

Lay, 4<sup>th</sup>, pg103, sec 2.2

# Characteristic Eqn and Polynomial

Recall that

$$\det \begin{bmatrix} a & b \\ c & d \end{bmatrix} = ad - bc$$

So

$$\begin{aligned} \det(A - \lambda I) &= (2 - \lambda)(-6 - \lambda) - (3)(3) \\ &= -12 + 6\lambda - 2\lambda + \lambda^2 - 9 \\ &= \lambda^2 + 4\lambda - 21 \\ &= (\lambda - 3)(\lambda + 7) \end{aligned}$$

If  $\det(A - \lambda I) = 0$ , then  $\lambda = 3$  or  $\lambda = -7$ . So the eigenvalues of  $A$  are 3 and  $-7$ . ■

Characteristic Eqn

Characteristic  
Polynomial

# Equivalent statements regarding eigenvalue $\lambda$

Given  $Ax = \lambda x$ , the following theorem applies:

**Theorem** Given a square matrix  $A$  and a scalar  $\lambda$ , the following statements are equivalent:

- $\lambda$  is an eigenvalue of  $A$ ,
- $N(A - \lambda I) \neq \{\mathbf{0}\}$ ,
- the matrix  $A - \lambda I$  is singular,
- $\det(A - \lambda I) = 0$ .

Ref: <https://textbooks.math.gatech.edu/ila/characteristic-polynomial.html>

# Example: EigenValues of Triangular Matrixes

## THEOREM 1

The eigenvalues of a triangular matrix are the entries on its main diagonal.

**PROOF** For simplicity, consider the  $3 \times 3$  case. If  $A$  is upper triangular, then  $A - \lambda I$  has the form

$$\begin{aligned} A - \lambda I &= \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ 0 & a_{22} & a_{23} \\ 0 & 0 & a_{33} \end{bmatrix} - \begin{bmatrix} \lambda & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \lambda \end{bmatrix} \\ &= \begin{bmatrix} a_{11} - \lambda & a_{12} & a_{13} \\ 0 & a_{22} - \lambda & a_{23} \\ 0 & 0 & a_{33} - \lambda \end{bmatrix} \end{aligned}$$

The scalar  $\lambda$  is an eigenvalue of  $A$  if and only if the equation  $(A - \lambda I)\mathbf{x} = \mathbf{0}$  has a nontrivial solution, that is, if and only if the equation has a free variable. Because of the zero entries in  $A - \lambda I$ , it is easy to see that  $(A - \lambda I)\mathbf{x} = \mathbf{0}$  has a free variable if and only if at least one of the entries on the diagonal of  $A - \lambda I$  is zero. This happens if and only if  $\lambda$  equals one of the entries  $a_{11}$ ,  $a_{22}$ ,  $a_{33}$  in  $A$ . For the case in which  $A$  is lower triangular, see Exercise 28. ■

## THEOREM 3.2 Determinant of a Triangular Matrix

If  $A$  is a triangular matrix of order  $n$ , then its determinant is the product of the entries on the main diagonal. That is,

$$\det(A) = |A| = a_{11}a_{22}a_{33} \cdots a_{nn}.$$

**Fact 7.** The determinant of a lower triangular matrix (or an upper triangular matrix) is the product of the diagonal entries. In particular, the determinant of a diagonal matrix is the product of the diagonal entries.

Proof: Khan's academy  
determinant of triangular  
matrix.

<https://www.khanacademy.org/math/linear-algebra/matrix-transformations/determinant-depth/v/linear-algebra-upper-triangular-determinant>

# Example: Meaning of eigenvalue == 0 => not invertible matrix

**EXAMPLE 5** Let  $A = \begin{bmatrix} 3 & 6 & -8 \\ 0 & 0 & 6 \\ 0 & 0 & 2 \end{bmatrix}$  and  $B = \begin{bmatrix} 4 & 0 & 0 \\ -2 & 1 & 0 \\ 5 & 3 & 4 \end{bmatrix}$ . The eigenvalues of  $A$  are 3, 0, and 2. The eigenvalues of  $B$  are 4 and 1. ■

What does it mean for a matrix  $A$  to have an eigenvalue of 0, such as in Example 5? This happens if and only if the equation

$$A\mathbf{x} = 0\mathbf{x} \quad (4)$$

has a nontrivial solution. But (4) is equivalent to  $A\mathbf{x} = \mathbf{0}$ , which has a nontrivial solution if and only if  $A$  is not invertible. Thus 0 is an eigenvalue of  $A$  if and only if  $A$  is not invertible. This fact will be added to the Invertible Matrix Theorem in Section 5.2.

## THEOREM

### The Invertible Matrix Theorem (continued)

Let  $A$  be an  $n \times n$  matrix. Then  $A$  is invertible if and only if:

- s. The number 0 is *not* an eigenvalue of  $A$ .
- t. The determinant of  $A$  is *not* zero.

# Example: eigenvalue and algebraic multiplicity

## EXAMPLE 3

Find the characteristic equation of

$$A = \begin{bmatrix} 5 & -2 & 6 & -1 \\ 0 & 3 & -8 & 0 \\ 0 & 0 & 5 & 4 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

**SOLUTION** Form  $A - \lambda I$ , and use Theorem 3(d):

$$\begin{aligned} \det(A - \lambda I) &= \det \begin{bmatrix} 5 - \lambda & -2 & 6 & -1 \\ 0 & 3 - \lambda & -8 & 0 \\ 0 & 0 & 5 - \lambda & 4 \\ 0 & 0 & 0 & 1 - \lambda \end{bmatrix} \\ &= (5 - \lambda)(3 - \lambda)(5 - \lambda)(1 - \lambda) \end{aligned}$$

The characteristic equation is

$$(5 - \lambda)^2(3 - \lambda)(1 - \lambda) = 0$$

or

$$(\lambda - 5)^2(\lambda - 3)(\lambda - 1) = 0$$

Expanding the product, we can also write

$$\lambda^4 - 14\lambda^3 + 68\lambda^2 - 130\lambda + 75 = 0$$

The eigenvalue 5 in Example 3 is said to have *multiplicity* 2 because  $(\lambda - 5)$  occurs two times as a factor of the characteristic polynomial. In general, the **(algebraic) multiplicity** of an eigenvalue  $\lambda$  is its multiplicity as a root of the characteristic equation.

# EigenValues and Algebraic multiplicity

**EXAMPLE 4** The characteristic polynomial of a  $6 \times 6$  matrix is  $\lambda^6 - 4\lambda^5 - 12\lambda^4$ . Find the eigenvalues and their multiplicities.

**SOLUTION** Factor the polynomial

$$\lambda^6 - 4\lambda^5 - 12\lambda^4 = \lambda^4(\lambda^2 - 4\lambda - 12) = \lambda^4(\lambda - 6)(\lambda + 2)$$

The eigenvalues are 0 (multiplicity 4), 6 (multiplicity 1), and  $-2$  (multiplicity 1). ■

The **set of solutions**  $(\lambda_1, \lambda_2, \dots, \lambda_{N_\lambda})$ , that is, the **eigenvalues**, is called the **spectrum** of  $A$ . The characteristic polynomial can be factored as follows:

$$p(\lambda) = (\lambda - \lambda_1)^{n_1} (\lambda - \lambda_2)^{n_2} \dots (\lambda - \lambda_{N_\lambda})^{n_{N_\lambda}} = 0.$$

The integer  $n_i$  is termed the **algebraic multiplicity** of eigenvalue  $\lambda_i$ . It is the number of times an eigenvalue appears as a root of the characteristic polynomial.

The algebraic multiplicities sum to  $N$  (the number of rows in  $A$ ):

$$\sum_{i=1}^{N_\lambda} n_i = N.$$

For each eigenvalue  $\lambda_i$ , there is a corresponding **EigenSpace**  $E(\lambda_i)$
